

## Homework 8 — Multiple Choice

ChE 132A

### Exercise 8 (Conservation of energy and the heat equation).

A solid (density  $\rho$ , heat capacity  $\hat{C}_P$ , conductivity  $k$ ) has volumetric heat-generation rate  $\dot{q}$  and no fluid motion. The integral energy balance for a fixed control volume  $V$  with boundary  $S$  is

$$\frac{d}{dt} \int_V \rho \hat{C}_P T dV = - \int_S \mathbf{n} \cdot \mathbf{q} dS + \int_V \dot{q} dV$$

(a) Because  $V$  is fixed, the time derivative on the LHS commutes with the volume integral, giving

- (A)  $\int_S \rho \hat{C}_P (\partial T / \partial t) dS$
- (B)  $\int_V \rho \hat{C}_P (\partial T / \partial t) dV$
- (C)  $\rho \hat{C}_P (\partial T / \partial t)$  (a single number, not an integral)
- (D)  $\int_V (\partial / \partial t) (T \rho \hat{C}_P dV)$ , with  $dV$  also differentiated

(b) Applying the divergence theorem to the surface integral converts it to

- (A)  $\int_V \mathbf{n} \cdot \mathbf{q} dV$
- (B)  $\int_V \nabla \cdot \mathbf{q} dV$
- (C)  $\int_S \nabla \cdot \mathbf{q} dS$
- (D)  $\int_S \mathbf{q} dS$  (no change)

(c) Substituting Fourier's law  $\mathbf{q} = -k \nabla T$  replaces  $-\nabla \cdot \mathbf{q}$  by  $\nabla \cdot (k \nabla T) = k \nabla^2 T$  (constant  $k$ ). The integral identity holds for arbitrary  $V$ , so the integrand vanishes pointwise, giving the heat equation

- (A)  $\rho \hat{C}_P \partial T / \partial t = -k \nabla^2 T + \dot{q}$
- (B)  $\rho \hat{C}_P \partial T / \partial t = k \nabla^2 T + \dot{q}$
- (C)  $\rho \hat{C}_P (\partial T / \partial t)^2 = k \nabla^2 T$
- (D)  $\rho \hat{C}_P \nabla T = k \partial T / \partial t$

(d) Dividing by  $\rho \hat{C}_P$  and comparing with the species mass-balance PDE  $\partial c_A / \partial t = D_A \nabla^2 c_A + R_A$  (no convection), the role of the diffusivity  $D_A$  is played by

- (A)  $k$
- (B)  $\rho \hat{C}_P$
- (C) the thermal diffusivity  $\alpha = k / (\rho \hat{C}_P)$
- (D)  $\dot{q} / (\rho \hat{C}_P)$

(e) For unidirectional flow of an incompressible Newtonian fluid the streamwise momentum equation reduces to  $\partial u / \partial t = \nu \partial^2 u / \partial y^2$ . The kinematic viscosity  $\nu = \mu / \rho$  here plays the role of

- (A) the source term  $\dot{q}/(\rho\hat{C}_P)$
- (B) the thermal diffusivity  $\alpha$  — the momentum-diffusion timescale is set by  $\nu$  exactly as the heat-diffusion timescale is set by  $\alpha$
- (C) the temperature  $T$
- (D) the surface flux  $\mathbf{n} \cdot \mathbf{q}$

**Exercise 9 (Flux heating of a semi-infinite slab).**

A semi-infinite solid ( $x > 0$ ) at zero initial temperature is heated by applying a constant flux  $q_0$  at the surface  $x = 0$ . In the dimensionless variables  $\Theta = kT/q_0$ ,  $\tau = \alpha t$ , the problem is

$$\partial_\tau \Theta = \partial_x^2 \Theta, \quad -\partial_x \Theta|_{x=0} = 1, \quad \Theta(x, 0) = 0, \quad \Theta \rightarrow 0 \quad (x \rightarrow \infty)$$

- (a) The Laplace transform (in  $\tau$ ) of the PDE plus the bounded-as- $x \rightarrow \infty$  condition gives  $\bar{\Theta}(x, s) = A(s) e^{-x\sqrt{s}}$ . Applying the transformed flux BC  $-d\bar{\Theta}/dx|_0 = 1/s$  determines  $A(s)$  as
- (A)  $A(s) = 1/s$
  - (B)  $A(s) = 1/\sqrt{s}$
  - (C)  $A(s) = 1/s^{3/2}$
  - (D)  $A(s) = 1/s^2$
- (b) Differentiating  $\bar{\Theta} = e^{-x\sqrt{s}}/s^{3/2}$  once in  $x$  gives  $-\partial\bar{\Theta}/\partial x = e^{-x\sqrt{s}}/s$ , which inverts to
- (A)  $-\partial\Theta/\partial x = e^{-x^2/(4\tau)}$
  - (B)  $-\partial\Theta/\partial x = \operatorname{erfc}(x/(2\sqrt{\tau}))$
  - (C)  $-\partial\Theta/\partial x = 1 - \operatorname{erf}(x\sqrt{\tau})$
  - (D)  $-\partial\Theta/\partial x = 1$
- (c) Integrating  $-\partial\Theta/\partial x = \operatorname{erfc}(x/2\sqrt{\tau})$  from  $x$  to  $\infty$  (using  $\Theta \rightarrow 0$  at infinity) and integrating by parts gives
- (A)  $\Theta(x, \tau) = \operatorname{erfc}(x/2\sqrt{\tau})$
  - (B)  $\Theta(x, \tau) = 2\sqrt{\tau/\pi} e^{-x^2/(4\tau)} - x \operatorname{erfc}(x/2\sqrt{\tau})$
  - (C)  $\Theta(x, \tau) = \sqrt{\tau/\pi}$
  - (D)  $\Theta(x, \tau) = x \operatorname{erf}(x/2\sqrt{\tau})$
- (d) Setting  $x = 0$  in the closed-form solution shows that the surface temperature grows as
- (A) a constant (independent of  $\tau$ )
  - (B)  $\Theta(0, \tau) = 2\sqrt{\tau/\pi} \propto \sqrt{\tau}$
  - (C)  $\Theta(0, \tau) \propto \tau$
  - (D)  $\Theta(0, \tau) \propto e^\tau$

The  $\sqrt{\tau}$  growth is the hallmark of diffusive penetration with constant-flux forcing.

- (e) The problem has no intrinsic length scale (the slab is semi-infinite). The only length appearing in the solution is therefore

- (A) a fixed length built into the geometry
- (B) the diffusion length  $\sqrt{\tau} = \sqrt{\alpha t}$ , which grows in time
- (C)  $1/\sqrt{q_0}$
- (D) the wavelength of the boundary forcing

**Exercise 11 (Startup of plane Couette flow).**

A Newtonian fluid of kinematic viscosity  $\nu$  fills the gap between two parallel plates at  $y = 0$  (stationary) and  $y = L$ . At  $t = 0$  the upper plate is set in motion at constant velocity  $U_0$ . In the dimensionless variables  $\eta = y/L$ ,  $\tau = \nu t/L^2$ ,  $\hat{u} = u/U_0$ ,

$$\hat{u}_\tau = \hat{u}_{\eta\eta}, \quad \hat{u}(0, \tau) = 0, \quad \hat{u}(1, \tau) = 1, \quad \hat{u}(\eta, 0) = 0$$

The inhomogeneous BC at  $\eta = 1$  blocks a direct sine-series attack; we split off the steady piece first.

- (a) The steady particular solution  $\hat{u}_p(\eta)$  satisfies  $\hat{u}_p'' = 0$  with  $\hat{u}_p(0) = 0$  and  $\hat{u}_p(1) = 1$ . This is

- (A)  $\hat{u}_p = 1$
- (B)  $\hat{u}_p = \eta$
- (C)  $\hat{u}_p = \frac{1}{2}\eta(1 - \eta)$
- (D)  $\hat{u}_p = \sin(\pi\eta/2)$

the linear Couette profile.

- (b) Writing  $\hat{u} = \hat{u}_p + w$  and substituting, the transient correction  $w(\eta, \tau)$  satisfies

- (A)  $w_\tau = w_{\eta\eta}$  with  $w(0, \tau) = w(1, \tau) = 0$  and  $w(\eta, 0) = -\eta$
- (B)  $w_\tau = w_{\eta\eta}$  with  $w(0, \tau) = w(1, \tau) = 0$  and  $w(\eta, 0) = +\eta$
- (C)  $w_\tau = w_{\eta\eta}$  with  $w(0, \tau) = 0$ ,  $w(1, \tau) = 1$
- (D)  $w_\tau = -w_{\eta\eta}$  (a backwards heat equation)

- (c) Expanding  $w(\eta, 0) = -\eta$  in the sine basis on  $[0, 1]$ , the coefficients  $a_n = -2 \int_0^1 \eta \sin(n\pi\eta) d\eta$  evaluate to

- (A)  $a_n = -2/(n\pi)$
- (B)  $a_n = -2$  for all  $n$
- (C)  $a_n = 2(-1)^n/(n\pi)$
- (D)  $a_n = 4/(n\pi)$  for odd  $n$ , 0 for even  $n$

- (d) Assembling, the full solution is

- (A)  $\hat{u}(\eta, \tau) = \eta e^{-\pi^2\tau}$
- (B)  $\hat{u}(\eta, \tau) = \frac{4}{\pi} \sum_{n \text{ odd}} \frac{1}{n} e^{-n^2\pi^2\tau} \sin(n\pi\eta)$
- (C)  $\hat{u}(\eta, \tau) = \eta + \frac{2}{\pi} \sum_{n \geq 1} \frac{(-1)^n}{n} e^{-n^2\pi^2\tau} \sin(n\pi\eta)$
- (D)  $\hat{u}(\eta, \tau) = \eta(1 - e^{-\pi^2\tau})$

(e) As  $\tau \rightarrow \infty$  every transient mode decays and the velocity profile approaches

- (A)  $\hat{u} \rightarrow 0$  everywhere
- (B)  $\hat{u} \rightarrow 1$  everywhere
- (C)  $\hat{u} \rightarrow \eta$ , the linear Couette profile
- (D)  $\hat{u} \rightarrow (4/\pi) \eta$

The slowest-decaying transient mode has timescale  $\tau_1 = 1/\pi^2 \approx 0.10$ , so steady state is reached on the momentum-diffusion time  $L^2/\nu$ .
